SA5 Discussion

Within our tests, we scanned for different parts of speech in various sentences. The first set of tests (commented out, first part of main method) we were using the simple test sentences. In this case, our testLine attempts included sentences already existing in the simple test sentences file. The fileInput was standard, however. For the second half of our testing, we used the Brown files and were therefore able to use our own developed sentences in the testLine method. We used some that had parts of speech not established in the Brown files just to see what would print out, and we got fairly creative with it. Yet, most of our sentences used only parts of speech that were established in the Brown files, so the parts of speech printed reflected the entire sentence. Our fileInput method used the two Brown files and gave us a ratio as well as totals for both the “all” (total) and for the “right” (correct) labels. We commented out our console input just to see the ratio clearly when running right away, but it works and should be left uncommented.
